### Abstract

**Problem/Condition:** Since 1969, CDC has conducted abortion surveillance to document the number and characteristics of women obtaining legal induced abortions in the United States.

**Reporting Period Covered:** 2012.

**Description of System:** Each year, CDC requests abortion data from the central health agencies of 52 reporting areas (the 50 states, the District of Columbia, and New York City). The reporting areas provide this information voluntarily. For 2012, data were received from 49 reporting areas. For trend analysis, abortion data were evaluated from 47 areas that reported data every year during 2003–2012. Census and natality data, respectively, were used to calculate abortion rates (number of abortions per 1,000 women) and ratios (number of abortions per 1,000 live births).

**Results:** A total of 699,202 abortions were reported to CDC for 2012. Of these abortions, 98.4% were from the 47 reporting areas that provided data every year during 2003–2012. Among these same 47 reporting areas, the abortion rate for 2012 was 13.2 abortions per 1,000 women aged 15–44 years, and the abortion ratio was 210 abortions per 1,000 live births. From 2011 to 2012, the total number and ratio of reported abortions decreased 4% and the abortion rate decreased 5%. From 2003 to 2012, the total number, rate, and ratio of reported abortions decreased 17%, 18%, and 14%, respectively, and reached their lowest level in 2012 for the entire period of analysis (2003–2012).

In 2012 and throughout the period of analysis, women in their 20s accounted for the majority of abortions and had the highest abortion rates; women in their 30s and older accounted for a much smaller percentage of abortions and had lower abortion rates. In 2012, women aged 20–24 and 25–29 years accounted for 32.8% and 25.4% of all abortions, respectively, and had abortion rates of 23.3 and 18.9 abortions per 1,000 women aged 20–24 and 25–29 years, respectively. In contrast, women aged 30–34, 35–39, and ≥40 years accounted for 16.4%, 9.1%, and 3.7% of all abortions, respectively, and had abortion rates of 12.4, 7.3, and 2.8 abortions per 1,000 women aged 30–34 years, 35–39 years, and ≥40 years, respectively. Throughout the period of analysis, abortion rates decreased among women aged 20–24, 25–29, and 30–34 years by 24%, 18%, and 10%, respectively, whereas they increased among women aged ≥40 years by 8%.

In 2012, adolescents aged <15 and 15–19 years accounted for 0.4% and 12.2% of all abortions, respectively, and had abortion rates of 0.8 and 9.2 abortions per 1,000 adolescents aged <15 and 15–19 years, respectively. From 2003 to 2012, the percentage of abortions accounted for by adolescents aged 15–19 years decreased 27% and their abortion rate decreased 40%. These decreases were greater than the decreases for women in any older age group.

In contrast to the percentage distribution of abortions and abortion rates by age, abortion ratios in 2012 and throughout the entire period of analysis were highest among adolescents aged ≤19 years and lowest among women aged 30–39 years. Abortion ratios decreased from 2003 to 2012 for women in all age groups.

In 2012, the majority (65.8%) of abortions were performed by ≤8 weeks' gestation, and nearly all (91.4%) were performed by ≤13 weeks' gestation. Few abortions (7.2%) were performed between 14–20 weeks' gestation or at ≥21 weeks' gestation (1.3%). From 2003 to 2012, the percentage of all abortions performed at ≤8 weeks' gestation increased 7%; the percentage performed at >13 weeks remained consistently low (≤9.0%).

In 2012, among the 40 reporting areas that included medical (nonsurgical) abortion on their reporting form, a total of 69.4% of abortions were performed by curettage at ≤13 weeks' gestation, 20.8% were performed by early medical abortion (a nonsurgical abortion at ≤8 weeks' gestation), and 8.7% were performed by curettage at >13 weeks' gestation; all other methods were uncommon. Among abortions performed at ≤8 weeks' gestation that were eligible on the basis of gestational age for early medical abortion, 30.8% were completed by this method. The percentage of abortions reported as early medical abortions increased 10% from 2011 to 2012.

Deaths of women associated with complications from abortions for 2012 are being investigated as part of CDC's Pregnancy Mortality Surveillance System. In 2011, the most recent year for which data were available, two women were identified to have died as a result of complications from known legal induced abortions. No reported deaths were associated with known illegal induced abortions.

**Interpretation:** Among the 47 areas that reported data every year during 2003–2012, the notable decreases that occurred during 2008–2011 in the total number, rate, and ratio of reported abortions continued from 2011 to 2012 and resulted in historic lows for all three measures of abortion.

**Public Health Actions:** The data in this report can help to identify groups of women at greatest risk for abortion and can be used to guide and evaluate prevention efforts. Because unintended pregnancy is the major contributor to abortion, and unintended pregnancies are rare among women who use the most effective methods of contraception, increasing access to and use of these methods can help further reduce the number of unintended pregnancies, and therefore abortions, performed in the United States.

### Introduction

This report is based on abortion data for 2012 that were provided voluntarily to CDC by the central health agencies of 49 reporting areas (the District of Columbia [DC]; New York City; and 47 states; excludes California, Maryland, and New Hampshire). Data were obtained every year during 2003–2012 from 47 reporting areas (excludes California, Louisiana, Maryland, New Hampshire, and West Virginia) and were used for trend analyses. Since 1969, CDC has conducted abortion surveillance to document the number and characteristics of women obtaining legal induced abortions in the United States (1). Following

nationwide legalization of abortion in 1973, the total number, rate (number of abortions per 1,000 women aged 15–44 years), and ratio (number of abortions per 1,000 live births) of reported abortions increased rapidly, reaching the highest levels in the 1980s before decreasing at a slow yet steady pace (2–4). However, the incidence of abortion has varied considerably across demographic subpopulations (5–9). Moreover, during 2006–2008, a break occurred in the previously sustained pattern of decrease (10–13), but in all subsequent years has been followed by even greater decreases (14–17). Continued surveillance is needed to monitor long-term changes in the incidence of abortion in the United States.

## Methods

### Description of the Surveillance System

Each year, CDC requests tabulated data from the central health agencies of 52 reporting areas (the 50 states, DC, and New York City) to document the number and characteristics of women obtaining legal induced abortions in the United States. For the purpose of surveillance, a legal induced abortion\* is defined as an intervention performed by a licensed clinician (e.g., a physician, nurse-midwife, nurse practitioner, or physician assistant) that is intended to terminate a suspected or known ongoing intrauterine pregnancy and produce a nonviable fetus at any gestational age.

In most states, collection of abortion data is facilitated by the legal requirement for hospitals, facilities, and physicians to report all abortions to a central health agency (18). These central health agencies then voluntarily report the abortion data they have collected through their independent surveillance systems and provide only aggregate numbers to CDC (19). Although reporting to CDC is voluntary, most reporting areas provide their aggregate abortion numbers: during 2003–2012, a total of 47 reporting areas provided CDC a continuous annual record of abortion numbers,<sup>†</sup> and in 2012, CDC obtained aggregate abortion numbers from 49 reporting areas.<sup>§</sup>

Although CDC obtains aggregate abortion numbers from most of the central health agencies on an annual basis, the level of detail that it receives on the characteristics of women obtaining abortions varies considerably from year to year and by reporting area. To encourage more uniform collection of these details, CDC has collaborated with the National Association of Public Health Statistics and Information Systems to develop reporting standards and provide technical guidance for vital statistics personnel who collect and summarize abortion data within the United States. However, because the collection of abortion data is not federally mandated, many reporting areas do not collect or provide all the information included in this report.

### Variables and Categorization of Data

Each year, CDC sends suggested templates to the central health agencies for compilation of abortion data in aggregate. Aggregate abortion numbers, without individual-level records, are requested for the following variables:

- Maternal age in years (<15, 15–19 by individual year, 20–24, 25–29, 30–34, 35–39, or ≥40)
- Gestational age in weeks at the time of abortion (≤6, 7–20 by individual week, or ≥21)
- Race (black, white, or other, including Asian, Pacific Islander, other races, and multiple races)
- Ethnicity (Hispanic or non-Hispanic)
- Method type (curettage,<sup>¶</sup> intrauterine instillation, medical [nonsurgical] abortion, or hysterectomy/hysterotomy)
- Marital status (married [including currently married or separated] or unmarried [including never married, widowed, or divorced])
- Number of previous live births (0, 1, 2, 3, or ≥4)
- Number of previous abortions (0, 1, 2, or ≥3)
- Maternal residence (the state, reporting area, territory, or foreign country in which the woman obtaining the abortion lived; or, if additional details are unavailable, in-reporting area versus out-of-reporting area)

In addition to providing templates for compiling information on race and ethnicity as separate variables, CDC has provided alternative templates since 2001 for the tabulation of aggregate cross-classified race/ethnicity data. Before 2007, few reporting areas returned these alternative templates. Therefore, 2012 is the sixth year for which CDC has had sufficient data to report results by these cross-classified race/ethnicity categories (non-Hispanic white, non-Hispanic black, non-Hispanic other, and Hispanic).

Finally, both the original and alternative templates provided by CDC request that aggregate numbers for certain variables be cross-tabulated by a second variable. These cross-tabulations include gestational age (separately by age, by method type, by race, by ethnicity, and by race/ethnicity) and age and marital status (separately by race, by ethnicity, and by race/ethnicity).

In this report, medical abortions and abortions performed by curettage are further categorized by gestational age. For medical abortion, early medical abortion is defined as the administration of medication or medications (typically mifepristone followed by misoprostol) to induce an abortion at ≤8 weeks' gestation;<sup>\*\*</sup> medical abortion at >8 weeks' gestation is defined as the administration of medication or medications (typically vaginal prostaglandins) to induce an abortion at >8 weeks' gestation. For curettage, abortions are categorized as having been performed at ≤13 weeks' gestation or at >13 weeks' gestation because of differences in technique used before and after 13 weeks (21). Finally, because intrauterine instillations cannot be performed early in gestation, abortions reported to have been performed by intrauterine instillation at ≤12 weeks' gestation are excluded from calculation of the percentage of abortions by known method type.<sup>††</sup>

### Measures of Abortion

Four measures of abortion are presented in this report: 1) the total number of abortions in a given population, 2) the percentage of abortions obtained by women in a given population, 3) the abortion rate (number of abortions per 1,000 women aged 15–44 years or other specific group within a given population), and 4) the abortion ratio (number of abortions per 1,000 live births within a given population). Although total numbers and percentages are useful for determining how many women have obtained an abortion, abortion rates adjust for differences in population size and reflect how likely abortion is among women in particular groups. Abortion ratios measure the relative number of abortions compared with live births. Abortion ratios are influenced both by the proportion of pregnancies in a population that are unintended and the proportion of unintended pregnancies that end in abortion. Abortion ratios also are influenced by the proportion of intended pregnancies that end in abortion; however, intended pregnancies account for a very small percentage of abortions (<5%) (24).

U.S. Census Bureau estimates of the resident female population of the United States during 2003–2012, compiled by CDC, were used as the denominator for calculating abortion rates (25–34). Overall abortion rates were calculated from the population of women aged 15–44 years living in the areas that provided data. For adolescents aged <15 years, abortion rates were determined on the basis of the number of adolescents aged 13–14 years; similarly, for women aged ≥40 years, abortion rates were determined on the basis of the number of women aged 40–44 years. For the calculation of abortion ratios, live birth data were obtained from CDC natality files (35) and included births to women of all ages living in the reporting areas that provided abortion data.

### Data Presentation and Analysis

This report provides state-specific and overall abortion numbers, rates, and ratios for the 49 areas that reported to CDC for 2012 (excludes California, Maryland, and New Hampshire). In addition, this report describes the characteristics of women who obtained abortions in 2012. Because the completeness of reporting on the characteristics of women varies by year and by variable, this report only describes the characteristics of women obtaining abortions in areas that met reporting standards (i.e., reported at least 20 abortions, provided data categorized in accordance with surveillance variables, and had <15%

unknown values for a given characteristic). Cells with a value in the range of 1–4 have been suppressed to maintain confidentiality. In addition, abortion rates and ratios have been omitted for groups with <20 abortions because results are considered unstable (36).

Although most of the data in this report are presented by the reporting area in which the abortions were performed, 47 reporting areas also provided the number of abortions by maternal residence. However, two of these reporting areas (Illinois and Wisconsin) reported certain characteristics for in-state residents but not for out-of-state residents. Three other reporting areas (Iowa, Louisiana, and Massachusetts) provided only the total number of abortions for out-of-state residents without specifying individual states or areas of residence from which these women came. As a result, abortion statistics in this report by area of residence should be interpreted with caution as they are minimum estimates and might be disproportionately low for reporting areas from which many women travel to other states to obtain abortion services.

To evaluate overall trends in the number, rate, and ratio of reported abortions, annual data are presented for the 47 areas that reported every year during 2003–2012. Linear regression analysis was used to assess the overall rate of change among these areas during the entire 10 year period of analysis (2003–2012) and during the first and second half of the period of analysis (2003–2007 and 2008–2012). The percentage change in abortion measures from the most recent past year of available data (2011 to 2012), and from the beginning to the end of the 10-year period of analysis (2003 to 2012), also were calculated with the same 47 areas that provided data for every year included in this report.

For the analysis of certain additional variables (i.e., abortions by maternal age and gestational age), annual data are presented for areas that met reporting standards every year during 2003–2012, and the percentage change was calculated from the beginning to the end of the 10 year period of analysis (2003 to 2012), from the beginning to the end of the first and second half of this period (2003 to 2007 and 2008 to 2012), and from the most recent past year to the current year (2011 to 2012). For other variables (i.e., race-ethnicity, method for performing an abortion, marital status, number of previous abortions, and number of previous live births), annual data are not presented, and areas were included if they met reporting standards for the years needed for percentage change calculations. To evaluate trends in the use of different methods for performing an abortion, reporting areas were included only if they met reporting standards and if they specifically included medical abortion as a method on their reporting form.

Some of the 49 areas that reported for 2012 are not included in certain trend analyses because they did not report or did not meet reporting standards for  $\geq 1$  years. As a result, summary measures for comparisons over time might differ slightly from the point estimates presented for all areas that reported for 2012.

## Abortion Mortality

CDC has reported data on abortion-related deaths periodically since information on abortion mortality first was included in the 1972 abortion surveillance report (17,37). An abortion-related death is defined as a death resulting from a direct complication of an abortion (legal or illegal), an indirect complication caused by a chain of events initiated by an abortion, or an aggravation of a preexisting condition by the physiologic or psychologic effects of abortion (38). All deaths determined to be related causally to induced abortion are classified as abortion-related regardless of the time between the abortion and death. In addition, any pregnancy-related death in which the pregnancy outcome was induced abortion regardless of the causal relation between the abortion and the death is considered an abortion-related death. An abortion is defined as legal only if it is performed by a licensed clinician.

Since 1987, CDC has monitored abortion-related deaths through its Pregnancy Mortality Surveillance System (39). Sources of data for abortion-related deaths have included state vital records; media reports, including computerized searches of full-text newspaper and other print media databases; and individual case reports by public health agencies, including maternal mortality review committees, health care providers and provider organizations, private citizens and citizen groups. For each death that possibly is related to abortion, CDC requests clinical records and autopsy reports. Two medical epidemiologists independently review these reports to determine the cause of death and whether the death was abortion related. Discrepancies are discussed and resolved by consensus. Each death is categorized by abortion type as legal induced, illegal induced, spontaneous, or unknown type.

This report provides data on induced abortion-related deaths from the Pregnancy Mortality Surveillance System that occurred in 2011, the most recent year for which data are available. Data on induced abortion-related deaths that occurred during 1972–2010 already have been published (17), and possible abortion-related deaths that occurred during 2012 are under investigation. Abortion surveillance data reported to CDC during 1998–2011 cannot be used alone to calculate national case-fatality rates (number of legal induced abortion-related deaths per 100,000 reported legal induced abortions in the United States) because certain states\*\*\* did not report abortion data every year during this period. Thus, national legal induced abortion case-fatality rates were calculated with denominator data from a more complete source on the total number of abortions performed in the United States (14). Because rates based on a numerator of <20 deaths are highly variable (36), national legal induced abortion case-fatality rates were calculated for consecutive 5-year periods during 1973–2007 and a 4-year period during 2008–2011.

## Results

### U.S. Totals

Among the 49 reporting areas that provided data for 2012, a total of 699,202 abortions were reported. Of these abortions, a total of 688,149 (98.4%) were obtained from the 47 reporting areas that provided data every year during 2003–2012.††† These same 47 areas had an abortion rate of 13.2 abortions per 1,000 women aged 15–44 years and an abortion ratio of 210 abortions per 1,000 live births (Table 1). For all three measures of abortion, large decreases resulted in the lowest levels reported during the entire period of analysis. From 2011 to 2012, the total number of reported abortions decreased 4% (from 719,530), the abortion rate decreased 5% (from 13.9 abortions per 1,000 women aged 15–44 years), and the abortion ratio decreased 4% (from 219 abortions per 1,000 live births). From 2003 to 2012, among the same 47 areas that reported every year, the total number of reported abortions decreased 17% (from 826,036), the abortion rate decreased 18% (from 16.1 abortions per 1,000 women aged 15–44 years), and the abortion ratio decreased 14% (from 245 abortions per 1,000 live births) (Figure 1). Additionally, for all three measures of abortion the annual rate of decrease fitted from the regression analysis was greater during 2008–2012 than during 2003–2007. During 2008–2012, the number of reported abortions decreased by 31,698 abortions per year, the abortion rate decreased by 0.63 abortions per 1,000 women per year, and the abortion ratio decreased by 5.2 abortions per 1,000 live births per year. In contrast, during 2003–2007, the number of reported abortions increased by 248 abortions per year, the abortion rate decreased by 0.03 abortions per 1,000 women per year and the abortion ratio decreased by 3.6 abortions per 1,000 live births per year.

### Occurrence and Residence

Abortion numbers, rates, and ratios for 2012 have been calculated by individual state or reporting area of occurrence and the residence of the women who obtained the abortions (Table 2). By occurrence, a considerable range existed in the abortion rate (ranging from 3.6 abortions per 1,000 women aged 15–44 years in Mississippi to 25.8 in New York [city and state combined]), and the abortion ratio (ranging from 52 abortions per 1,000 live births in South Dakota to 433 in New York [city and state combined]). Similarly, a considerable range existed by residence in the abortion rate (ranging from 4.9 abortions per 1,000 women aged 15–44 years in South Dakota to 25.2 in New York [city and state combined]), and the abortion ratio (ranging from 61 abortions per 1,000 live births in Utah to 422 in New York [city and state combined]). Because of variation that occurred among reporting areas in the percentage of abortions obtained by out-of-state residents (ranging from 0.7% in Hawaii to 50.9% in Kansas), abortion rates and ratios calculated by maternal residence might provide a more accurate reflection of the state-specific distribution of women obtaining abortions. However, because states vary in the level of detail they collect on maternal residence, 12.4% of abortions were reported to CDC without exact information on maternal residence.

### Age

Among the 45 areas that reported by maternal age for 2012, women in their 20s accounted for the majority (58.2%) of abortions and had the highest abortion rates (23.3 and 18.9 abortions per 1,000 women aged 20–24 and 25–29 years, respectively) (Figure 2) (Table 3). Women in the youngest (<15 years) and oldest age groups (≥40 years) accounted for the smallest percentage of abortions (0.4% and 3.7%, respectively) and had the lowest abortion rates (0.8 and 2.8 abortions per 1,000 women aged <15 and ≥40 years, respectively). Among the 42 reporting areas that provided data every year during 2003–2012, this pattern across age groups was stable, with the majority of abortions and the highest abortion rates occurring among women in the 20s and the lowest percentages of abortions and abortion rates occurring among women in the youngest and oldest age groups (Table 4). However, from 2003 to 2012 the abortion rate and percentage of abortions accounted for by younger women decreased, whereas the abortion rate and percentage of abortions accounted for by older women increased. Decreases in the abortion rate were greatest for adolescents (43% and 40% for adolescents aged <15 and 15–19 years, respectively), but also were pronounced for women aged 20–34 years (24%, 18%, and 10% for women aged 20–24, 25–29, and 30–34 years, respectively). Among women in these age groups, decreases in the abortion rate were greater from 2008 to 2012 than from 2003 to 2007. In contrast, among women aged 35–39 years, abortion rates increased from 2003 to 2007 and then decreased from 2008 to 2012, resulting in an overall increase of 1%. Among women aged ≥40 years, abortion rates increased during both periods, resulting in an overall increase of 8%.

In contrast to the percentage distribution of abortion numbers and abortion rates, in 2012 abortion ratios were highest among adolescents aged ≤19 years and lowest among women aged 30–39 years (Figure 2) (Table 3). Among the 42 reporting areas that provided data for every year during 2003–2012, abortion ratios decreased among women in all age groups both from 2003 to 2007 and from 2008 to 2012 (Table 4).

## Adolescents

Among the 43 areas that reported age by individual year among adolescents for 2012, adolescents aged 18–19 years accounted for the majority (65.9%) of adolescent abortions and had the highest adolescent abortion rates (12.7 and 17.0 abortions per 1,000 adolescents aged 18 and 19 years, respectively); adolescents aged <15 years accounted for the smallest percentage of adolescent abortions (3.1%) and had the lowest adolescent abortion rate (0.7 abortions per 1,000 adolescents aged 13–14 years) (Table 5). Among the 40 reporting areas that provided data for adolescents by individual year of age every year during 2003–2012, the percentage of abortions accounted for by adolescents aged 19 years increased, and decreases in the abortion rate were greater for younger as compared with older adolescents (Table 6). Among adolescents of all ages, abortion rates decreased both from 2003 to 2007 and from 2008 to 2012; decreases were greatest from 2008 to 2012, and large decreases continued from 2011 to 2012.

In 2012, the abortion ratio for adolescents decreased with increasing age and was lowest among adolescents aged 19 years (Table 5). Among the 40 reporting areas that provided data for adolescents by individual year of age for every year during 2003–2012, abortion ratios decreased among adolescents of all ages (Table 6).

## Gestational Age

Among the 38 areas that reported gestational age at the time of abortion for 2012 (Table 7), two-thirds (65.8%) of abortions were performed by ≤8 weeks' gestation, and 91.4% were performed at ≤13 weeks' gestation. Few abortions were performed between 14–20 weeks' gestation (7.2%) or at ≥21 weeks' gestation (1.3%). Among the 30 reporting areas that provided data on gestational age every year during 2003–2012 (Table 8), the percentage of abortions performed at ≤13 weeks' gestation was comparatively stable. However, within this gestational age range, a shift occurred toward earlier gestational ages, with abortions performed at ≤8 weeks' gestation increasing 7% and abortions performed at 9–13 weeks decreasing 12%. Abortions performed at >13 weeks' gestation accounted for a small percentage of all abortions (≤9.0%) for the entire period during 2003–2012.

Among the subset of abortions performed at ≤13 weeks' gestation and reported by individual week of gestation for 2012, 38.2% were performed at ≤6 weeks' gestation (Table 9). Among the remaining abortions between 7 and 13 weeks' gestation, the percentage contribution was progressively lower for each additional week of gestation: 19.4% were performed at 7 weeks' gestation and 3.1% were performed at 13 weeks' gestation. Among the 30 areas that reported by exact week of gestation for abortions at ≤13 weeks' gestation every year during 2003–2012, the percentage of abortions shifted toward earlier gestational ages: those performed at ≤6 weeks' gestation increased 24%, and those performed at 7–12 weeks' gestation decreased up to 19% (Table 10).

## Method Type

Among the 40 areas that reported by method type for 2012 and included medical abortion on their reporting form for medical providers, 69.4% of abortions were performed by curettage at ≤13 weeks' gestation, 20.8% were performed by early medical abortion (a nonsurgical abortion at ≤8 weeks' gestation), and 8.7% were performed by curettage at >13 weeks' gestation; all other methods were uncommon (Table 11). Among the 30 reporting areas that included medical abortion on their reporting form and provided this data for the relevant years of comparison (2003 versus 2007, 2008 versus 2012, and 2011 versus 2012),<sup>††††</sup> use of early medical abortion increased 10% from 2011 to 2012 (from 18.5% of abortions in 2011 to 20.4% in 2012); from 2003 to 2012, use of early medical abortion increased 140% (from 8.5% of abortions in 2003 to 20.4% in 2012). Large increases in medical abortion occurred both from 2003 to 2007 (from 8.5% of abortions in 2003 to 12.2% in 2007 [44% increase]), and from 2008 to 2012 (from 14.4% of abortions in 2008 to 20.4% in 2012 [42% increase]). In contrast, use of curettage at ≤13 weeks' gestation decreased 14% (from 81.3% of abortions in 2003 to 69.9% in 2012). Curettage at >13 weeks' gestation consistently accounted for approximately 8% of abortions (8.6% in 2003 and 8.5% in 2012), and all other methods accounted for a small percentage of abortions (0.01%–1.1%) for the entire period during 2003–2012.

## Race/Ethnicity

Among the 27 areas that reported cross-classified race/ethnicity data for 2012 (Table 12), non-Hispanic white women and non-Hispanic black women accounted for the largest percentages of abortions (37.6% and 36.7%, respectively), and Hispanic women and non-Hispanic women in the other race category accounted for smaller percentages (18.7% and 7.0%, respectively). Non-Hispanic white women had the lowest abortion rate (7.7 abortions per 1,000 women aged 15–44 years) and ratio (127 abortions per 1,000 live births), and non-Hispanic black women had the highest abortion rate (27.8 abortions per 1,000 women aged 15–44 years) and ratio (435 abortions per 1,000 live births). Data for 2012 are also reported separately by race (Table 13) and by ethnicity (Table 14).

Among the 21 areas<sup>§§§§</sup> that reported by race/ethnicity for 2007 (the first year with available data), and 2012, abortion rates decreased substantially for all three major racial/ethnic groups, with the greatest decrease occurring among Hispanic women. For non-Hispanic white women, the abortion rate decreased 18% (from 9.3 abortions per 1,000 women in 2007 to 7.6 in 2012), for non-Hispanic black women it decreased 18% (from 34.8 abortions per 1,000 women in 2007 to 28.6 in 2012) and for Hispanic women it decreased 26% (from 20.7 abortions per 1,000 women in 2007 to 15.3 in 2012). For abortion ratios the largest decrease from 2007 to 2012 occurred among non-Hispanic white women. For non-Hispanic white women, the abortion ratio decreased 14% (from 144 abortions per 1,000 live births in 2007 to 124 in 2012), for non-Hispanic black women it decreased 9% (from 486 abortions per 1,000 live births in 2007 to 444 in 2012), and for Hispanic women it decreased 5% (from 204 abortions per 1,000 live births in 2007 to 194 in 2012).

## Marital Status

Among the 36 areas that reported by marital status for 2012, 14.7% of all women who obtained an abortion were married and 85.3% were unmarried (Table 15). The abortion ratio was 47 abortions per 1,000 live births for married women and 396 abortions per 1,000 live births for unmarried women. Among the 29 reporting areas<sup>¶¶¶¶</sup> that provided these data for the relevant years of comparison (2003 versus 2007, 2008 versus 2012, and 2011 versus 2012), the percentage of abortions among unmarried women increased 5% from 2003 to 2012 (from 81.8% in 2003 to 85.6% in 2012); increases from 2003 to 2007 and from 2008 to 2012 were similar. Among married women, the abortion ratio decreased 24% from 2003 to 2012 (from 55 to 42 abortions per 1,000 live

births), with a larger decrease occurring from 2008 to 2012 (14%) than from 2003 to 2007 (9%). Among unmarried women, the abortion ratio decreased 23% from 2003 to 2012 (from 478 to 366 abortions per 1,000 live births). For unmarried women, the decrease was greater from 2003 to 2007 (18%) than from 2008 to 2012 (8%).

### Previous Live Births and Abortions

Data from the 39 areas that reported the number of previous live births for women who obtained abortions in 2012 show that 40.3%, 45.8%, and 14.0% of these women had zero, one to two, or three or more previous live births, respectively (Table 16). Among the 36 reporting areas\*\*\*\* that provided these data for the relevant years of comparison (2003 versus 2007, 2008 versus 2012, and 2011 versus 2012), the percentage of women obtaining abortions who had no previous live births was comparatively stable; by contrast, the percentage decreased for women who had one to two previous live births, and increased for women who had three or more previous live births. Among the areas included in this comparison, 39.4%, 47.9%, and 12.7% of women had zero, one to two, or three or more previous live births, respectively, in 2003; 40.3%, 45.7%, and 14.0% of women had zero, one to two, or three or more live births, respectively, in 2012.

Data from the 38 areas that reported the number of previous abortions for women who obtained abortions in 2012 indicate that the majority (55.7%) had no previous abortions, 35.6% had one to two previous abortions, and 8.6% had three or more previous abortions (Table 17). Among the 31 reporting areas++++ that provided data for the relevant years of comparison (2003 versus 2007, 2008 versus 2012, and 2011 versus 2012), the percentage of women who had zero or one to two previous abortions was comparatively stable; there was an increase from 2003 to 2012 in the percentage of women who had three or more previous abortions, but the percentages leveled off from 2011 to 2012. Among the areas included in this comparison, 55.1%, 36.9%, and 8.0% of women had zero, one to two, or three or more previous abortions, respectively, in 2003; by contrast, 53.4%, 37.0%, and 9.6% of women had zero, one to two, or three or more previous abortions, respectively, in 2011, and 54.3%, 36.2%, and 9.5% of women had zero, one to two, or three or more previous abortions, respectively, in 2012.

### Age and Marital Status by Race/Ethnicity

In certain reporting areas, abortions that were categorized by maternal race and race/ethnicity were further categorized by maternal age and by marital status (Tables 18 and 19). A consistent pattern existed for abortions by age across all race/ethnicity groups, with the smallest percentage of abortions occurring among adolescents aged <15 years (0.3%–0.5%) and the largest percentage occurring among women aged 20–24 years (27.0%–33.6%) (Table 19). A consistent pattern also existed for abortions by marital status across all race/ethnicity groups, with a higher percentage of abortions occurring among women who were unmarried (67.5%–91.1%) than among those who were married (8.9%–32.5%) (Table 19). However, for abortions among unmarried women, the percentage was higher for non-Hispanic black women (91.1%) than for non-Hispanic white (82.9%) or Hispanic women (83.9%) (Table 19).

### Weeks of Gestation by Age, Race/Ethnicity, and Method Type

In certain reporting areas, abortions that were categorized by weeks of gestation were further categorized by maternal age, race, and race/ethnicity (Tables 20 and 21). In every subgroup for these three variables, the largest percentage of abortions was obtained at ≤8 weeks' gestation (Table 20). However, a greater percentage of women in younger age groups obtained abortions at later gestational ages: 45.7% of adolescents <15 years and 56.2% of adolescents 15–19 years obtained an abortion by ≤8 weeks' gestation, compared with 63.6%–71.7% of women in older age groups (Figure 3). Conversely, 20.6% of adolescents aged <15 years and 12.4% of adolescents 15–19 years obtained an abortion after 13 weeks' gestation, compared with 7.2%–9.0% for women in older age groups. By race/ethnicity, 60.0% of non-Hispanic black women obtained an abortion at ≤8 weeks' gestation, compared with 68.5%–72.2% of women from other racial/ethnic groups. Non-Hispanic black women obtained the highest percentage of abortions after 13 weeks' gestation, but differences across racial/ethnic groups were less apparent than differences across age groups (9.7% for non-Hispanic black women, compared with 7.3%–8.4% for women in the remaining race-ethnicity groups).

Among abortions categorized by method type and gestational age, curettage accounted for the largest percentage of abortions within every gestational age category (Table 22). At ≤8 weeks' gestation, curettage accounted for a smaller percentage of abortions (69.2%) than at any other stage of gestation. At 9–20 weeks' gestation, curettage accounted for 96.6%–99.3% of all abortions and then decreased to 93.2% of abortions at ≥21 weeks' gestation. By contrast, at ≤8 weeks' gestation, early medical abortion accounted for 30.8% of abortions, but at all subsequent points in gestation the use of medications to induce abortions through nonsurgical methods accounted for only 0.5%–6.2% of reported abortions. Throughout gestation, abortions performed by intrauterine instillation or hysterectomy/hysterotomy were rare (<0.01%–0.5% of all abortions).

### Abortion Mortality

Using national data from the Pregnancy Mortality Surveillance System (39), CDC identified two abortion-related deaths for 2011 (Table 23). These deaths were identified either by some indication of abortion on the death certificate, by reports from a health care provider or public health agency, or from a media report. Investigation of these cases indicated that both deaths were related to legal abortion and neither to illegal abortion.

The annual number of deaths related to legal induced abortions has fluctuated from year to year over the past 38 years (Table 23). For example, 12 induced abortion-related deaths occurred in 1994, four deaths in 1995, and nine deaths in 1996. Because of this variability and the relatively small number of legal induced abortion-related deaths every year, national legal abortion case-fatality rates were calculated for consecutive 5-year periods during 1973–2007 and a 4-year period during 2008–2011. The national legal induced abortion case-fatality rate for 2008–2011 was 0.73 legal induced abortion-related deaths per 100,000 reported legal abortions. This case fatality rate was similar to the rate for most of the preceding 5-year periods but lower than the case-fatality rate of 2.09 legal induced abortion-related deaths per 100,000 reported legal abortions for the 5-year period (1973–1977) immediately following nationwide legalization of abortion in 1973. Possible abortion-related deaths that occurred during 2012–2015 are under investigation.

### Discussion

For 2012, a total of 699,202 abortions were reported to CDC. Of these abortions, 688,149 (98.4%) were from 47 reporting areas that submitted data every year during 2003–2012, thus providing the information necessary for evaluating trends. These 47 areas had an abortion rate of 13.2 abortions per 1,000 women aged 15–44 years and an abortion ratio of 210 abortions per 1,000 live births. Compared with 2011, this represents a 4% decrease in the total number (from 719,530) and ratio (from 219 abortions per 1,000 births), and a 5% decrease in the rate (from 13.9 abortions per 1,000 women) of reported abortions among the 47 continuously reporting areas. Because of the size of these decreases, combined with large decreases from the previous 3 years (15–17), all three measures of abortion reached their lowest level for the entire period of analysis (2003–2012).

In addition to highlighting changes that occurred among all women of reproductive age, this report underscores important age differences in abortion trends. During 2003–2012, women in their 20s consistently accounted for the majority of abortions (56%–58%) and therefore have contributed substantially to overall changes in abortion rates. Conversely, women aged ≥40 years consistently have accounted for a small percentage of abortions (≤3.7% during 2003–2012) and have had a much smaller contribution to overall abortion trends. Nonetheless, among women aged ≥40 years, abortion rates have shown an overall increase and the abortion ratio for this age group remains high. Together with the continuing small proportion of abortions performed later in gestation among these women, which potentially might be completed for maternal medical indications or fetal anomalies, these patterns suggest that unintended pregnancy is a problem that women encounter throughout their reproductive years.

The adolescent abortion trends described in this report are important for monitoring progress that has been made toward reducing adolescent pregnancies in the United States. During 1990–2009, the pregnancy rate for adolescents aged 15–19 years decreased 44% to an historic low (40). This decrease was associated with substantial decreases in both the rate of live births (58%) and abortions (60%) among adolescents (40). More recent data indicate that the birth rate for adolescents aged 15–19 years decreased by a further 29% from 2010 to 2014 (41–45). The 12% decrease from 2011 to 2012 in the adolescent abortion rate suggests that adolescent pregnancies in the United States are continuing to decrease and that this decrease continues to be accompanied by substantial decreases in adolescent abortions as well as live births.

The findings in this report indicate that the number, rate, and ratio of reported abortions has declined across all race/ethnicity groups, but that well-documented disparities (3–9) continue to persist. Comparatively high abortion rates and ratios among non-Hispanic black women have been attributed to higher unintended pregnancy rates and a higher percentage of unintended pregnancies ending in abortion (46,47). Data from certain recent reports suggest that differences in abortion between non-Hispanic black women and women of other races have narrowed (8,9). However, this pattern has not been observed in the data reported to CDC for 2012 or in previous years with similar declines among non-Hispanic white and black women. Higher abortion rates among Hispanic compared with non-Hispanic white women have been attributed to high pregnancy rates, including intended and unintended pregnancies, among Hispanic women (46,47). However, abortion ratios in these two groups have been more comparable: Hispanic women have had a slightly higher percentage of pregnancies that are unintended but are no more likely than non-Hispanic white women to end unintended pregnancies in abortion (46,47). Differences between non-Hispanic white and Hispanic women in abortion rates changed little from 2007 to 2012, with large declines again occurring in both groups of women.

The findings in this report indicate women are obtaining abortions earlier in gestation, when the risks for complications are lowest (48–51). Among the areas that reported data every year during 2003–2012, the percentage of abortions performed at ≤8 weeks' gestation increased 7%. Moreover, among the areas that reported abortions at ≤13 weeks' gestation by individual week, the distribution continued to shift toward earlier weeks of gestation with the percentage of early abortions performed at ≤6 weeks' gestation increasing 24%. Nonetheless, the overall percentage of abortions performed at ≤13 weeks' gestation changed little during 2003–2012, and findings from this and other reports suggest that delays in obtaining an abortion are more common among certain groups of women (52–54). Because of the small but persistent percentage of women who obtain abortions at >13 weeks' gestation, a better understanding is needed of the factors that cause delays in obtaining abortions (52,54–58).

The trend of obtaining abortions earlier in pregnancy has been facilitated by changes in abortion practices. Research conducted in the United States during the 1970s indicated that surgical abortion procedures performed at ≤6 weeks' as compared with 7–12 weeks' gestation were less likely to result in successful termination of the pregnancy (58). However, subsequent advances in technology (e.g., improved transvaginal ultrasonography and sensitive pregnancy tests) have allowed very early surgical abortions to be performed with completion rates exceeding 97% (51,59–61). Likewise, the development of medical abortion regimens has allowed for abortions to be performed very early in gestation, with completion rates for regimens that combine mifepristone and misoprostol reaching 96%–98% (62). In 2012, 65.8% of abortions were performed at ≤8 weeks' gestation, and thus the women receiving these abortions were eligible for early medical abortion on the basis of gestational age; 30.8% of these abortions at ≤8 weeks' gestation and 20.8% of all abortions were reported as early medical abortions. Moreover, the use of early medical abortion has continued to rise: from 2003 to 2012, the percentage of all reported abortions accounted for by this method increased 140%, with large increases observed both from 2003 to 2007 and 2008 to 2012.

The annual number of deaths related to legal induced abortions has fluctuated annually during 1973–2011. Because of this variability and the relatively small number of abortion-related deaths every year, national legal abortion case-fatality rates were calculated for consecutive 5-year periods during 1973–2007 and a 4-year period during 2008–2011. The national legal induced abortion case-fatality rate for 2008–2011 was similar to the case fatality rate for most of the preceding 5-year periods, but was much lower than the case fatality year for the period of 1973–1977 that immediately followed nationwide legalization of abortion in 1973.

## Limitations

The findings in this report are subject to at least four limitations. First, because reporting requirements are established by the individual reporting areas (19), the collection of data varies, and CDC is unable to obtain the total number of abortions performed in the United States. During the period covered by this report, the total annual number of abortions reported to CDC was consistently approximately 70% of the number recorded by the Guttmacher Institute (14,63), which uses numerous active follow-up techniques to increase the completeness of the data obtained through its periodic national census of abortion providers (14). Although most reporting areas collect and send abortion data to CDC, this information is submitted to CDC voluntarily. Consequently, during 2003–2012, five of the 52 reporting areas did not provide CDC data on a consistent annual basis, and for 2012, CDC did not obtain any information from California, Maryland, or New Hampshire. In addition, whereas most reporting areas that send abortion data to CDC have laws requiring medical providers to submit a report for every abortion they perform to a central health agency, in New Jersey and DC, medical providers submit this information voluntarily (18). As a result, the abortion numbers these areas report to CDC are incomplete. Moreover, even in states that legally require medical providers to submit a report for all the abortions they perform, enforcement of this requirement varies and as a consequence several other reporting areas tend to provide CDC with incomplete numbers.\*\*\*\*\*

Second, because reporting requirements are established by the individual reporting areas, many states use reporting forms that do not follow the technical standards and guidance CDC developed in collaboration with the National Association of Public Health Statistics and Information Systems. Consequently, many reporting areas do not collect all the information CDC compiles on the characteristics of women obtaining abortions (e.g., age, race, and ethnicity). Although missing demographic information can reduce the extent to which the statistics in this report represent all women in the United States, four nationally representative surveys of women obtaining abortions in 1987, 1994–1995, 2001–2002, and 2008 (5–8) have produced percentage distributions for most characteristics that are nearly identical to the percentage distributions reported by CDC. The one exception is the percentage distribution of abortions by race/ethnicity. In particular, the percentage of abortions accounted for by non-Hispanic black women is higher in this report than the percentage on the basis of a recent nationally representative survey of women obtaining abortions (8). Similarly, the greater decrease in abortion rates for non-Hispanic black women compared with women of other racial/ethnic groups on the basis of nationally representative survey data (9) is not supported by the data reported to CDC. These differences likely are attributable both to the high degree of measurement error for this variable that reduces the reliability of national survey results (8,9) and because the number of states that report to CDC by race/ethnicity continues to be somewhat lower than for other demographic variables. Importantly, some reporting areas that have not reported to CDC, or have not reported cross-classified race/ethnicity data (e.g., California, Florida, and Illinois), have sufficiently large populations of minority women that the absence of data from these areas reduces the representativeness of CDC data.

Similar to the case for race/ethnicity, the absence of medical abortion as a specific category on the reporting form used by some states (18) might reduce the precision of CDC's estimates of the use of this method relative to other abortion techniques. Furthermore, even in states with medical abortion on their reporting form, it is possible that this method is disproportionately undercounted: a higher percentage of the abortions provided in physician's offices and smaller caseload facilities are medical abortions (13,64), and these practices might be difficult to locate in the wider medical community without active surveillance efforts (64). Nonetheless, a recent comparison of CDC data with mifepristone sales data<sup>+++++</sup> suggests that CDC's Abortion Surveillance System accurately describes the use of medical abortion relative to other abortion methods in the United States (65).

Third, abortion data are compiled and reported to CDC by the central health agency of the reporting area in which the abortion was performed rather than the reporting area in which the woman lived. Thus, the available population (25–34) and birth data (35), which are organized by the states in which women

live, might differ in some cases from the population of women seeking abortions in a given reporting area. This likely results in an overestimation of abortions for reporting areas in which a high percentage of abortions are obtained by out-of-state residents and an underestimation of abortions for states with limited abortion services, more stringent legal requirements for obtaining an abortion, or geographic proximity to services in another state. To adjust for these reporting biases, CDC attempts to categorize abortions by residence in addition to geographic occurrence. However, in 2012, CDC was unable to identify the reporting area, territory, or country of residence for 12.4% of reported abortions.

Finally, reporting areas provide CDC with aggregate numbers rather than individual-level records. Because CDC does not obtain individual-level records, stratified analyses by socioeconomic status cannot be done.

## Public Health Implications

Ongoing surveillance of legal induced abortions is important for several reasons. First, abortion surveillance is needed to guide and evaluate the success of programs aimed at preventing unintended pregnancies. Although pregnancy intentions are difficult to assess (66–73), abortion surveillance provides an important measure of pregnancies that are unwanted. Second, routine abortion surveillance is needed to assess trends in clinical practice patterns over time. Information in this report on the number of abortions performed through different methods (e.g., medical or curettage) and at different gestational ages provides the denominator data that are necessary for analyses of the relative safety of abortion practices. Finally, information on the number of pregnancies ending in abortion are needed in conjunction with data on births and fetal losses to more accurately estimate the overall number of pregnancies in the United States as well as rates by various characteristics (e.g., adolescents) (40,74).

According to the most recent national estimates, 18% of all pregnancies in the United States end in abortion (40). Multiple factors influence the incidence of abortion including the availability of abortion providers (13,14,75–77); state regulations, such as mandatory waiting periods (78), parental involvement laws (79), and legal restrictions on abortion providers (80,81); increasing acceptance of nonmarital childbearing (82,83); shifts in the racial/ethnic composition of the U.S. population (84,85); and changes in the economy and the resulting impact on fertility preferences and access to health care services, including contraception (86,87). However, because unintended pregnancy precedes nearly all abortions (24),§§§§§§ efforts to reduce the incidence of abortion need to focus on helping women, men, and couples avoid pregnancies that they do not desire.

Providing women and men with the knowledge and resources necessary to make decisions about their sexual behavior and use of contraception can help them avoid unintended pregnancies. However, efforts to improve contraceptive use and reduce the proportion of pregnancies that are unintended in the United States have been challenging. Findings from the National Survey of Family Growth (NSFG), the primary national source of data on unintended pregnancy in the United States, suggest that unintended pregnancy decreased during 1982–1995 in conjunction with an increase in contraceptive use among women at risk for unintended pregnancy (88–90). However, data from the 2002 and 2006–2010 NSFGs indicate little further improvement in contraceptive use (89,91). Moreover, although use of the most effective forms of reversible contraception (i.e., intrauterine devices and hormonal implants, which are as effective as sterilization at preventing unintended pregnancy) (92) has increased (93–95), use of these methods in the United States remains among the lowest of any developed country (94,96), and the percentage of pregnancies that are unintended remains high at approximately 50% (46,47). Research has shown that providing contraception for women at no cost increases use of the most effective methods and can reduce abortion rates (97,98). Removing cost as a barrier and increasing access to the most effective contraceptive methods can help to reduce the number of unintended pregnancies and consequently the number of abortions performed in the United States.

\* Hereafter, all abortions in this report are considered to be legally induced unless stated to be illegally induced.

† Data were not reported for ≥1 year by California (2003–2012), Louisiana (2005), Maryland (2007–2012), New Hampshire (2003–2012), and West Virginia (2003–2004).

§ Data were not reported for 2012 by California, Maryland, or New Hampshire.

¶ Includes aspiration curettage, suction curettage, manual vacuum aspiration, menstrual extraction, sharp curettage, and dilation and evacuation procedures.

\*\* CDC collects information only on the estimated number of weeks (not days) of gestation and acknowledges the conventional use of completed weeks of gestation to describe pregnancy duration. CDC's category "≤8 weeks' gestation" thus includes abortions up through 8 weeks and 6 days, which closely corresponds to the gestational age limit of 63 days for the early medical abortion protocol that was endorsed by the American College of Obstetricians and Gynecologists during the year encompassed by this surveillance report (20).

†† The cutoff of ≤12 weeks has been selected on the basis of the implausibility of this procedure being performed at earlier gestational ages, and on the basis of early research assessing the safety of intrauterine instillations starting at 13 weeks' gestation (22,23).

§§ Excludes five reporting areas that did not report or did not report by maternal residence (California, DC, Florida, Maryland, and New Hampshire).

¶¶ Excludes California, Louisiana, Maryland, New Hampshire, and West Virginia.

\*\*\* States that did not report for ≥1 year since 1998 include Alaska (1998–2000), California (1998–2011), Louisiana (2005), Maryland (2007–2011), New Hampshire (1998–2011), Oklahoma (1998–1999), and West Virginia (2004–2005).

††† Excludes California, Louisiana, Maryland, New Hampshire, and West Virginia.

§§§ Comparisons do not include Wyoming, which reported <20 abortions.

¶¶¶ Comparisons by residence status do not include California, DC, Florida, Maryland, or New Hampshire because these areas either did not report or did not report abortions by maternal residence. Consequently, numbers for these reporting areas are available only from other states where their residents obtained abortions, and are not complete.

\*\*\*\* Comparisons by residence status also exclude Maine. Data from this state are preliminary because of incomplete reporting from certain facilities.

†††† Excludes Alabama, Arizona, California, Colorado, DC, Florida, Georgia, Hawaii, Illinois, Iowa, Kentucky, Louisiana, Maine, Maryland, Nevada, New Hampshire, Rhode Island, Tennessee, Vermont, West Virginia, Wisconsin, and Wyoming.

§§§§ Excludes Alaska, Arizona, California, Connecticut, Delaware, DC, Florida, Hawaii, Illinois, Iowa, Kentucky, Louisiana, Maine, Maryland, Massachusetts, Michigan, Nebraska, Nevada, New Hampshire, New Mexico, New York State, North Carolina, North Dakota, Oklahoma, Pennsylvania, Rhode Island, South Carolina, Vermont, Washington, Wisconsin, and Wyoming.

¶¶¶¶ Excludes Arkansas, California, Connecticut, DC, Florida, Georgia, Iowa, Louisiana, Maine, Maryland, Massachusetts, Montana, Nebraska, Nevada, New Hampshire, New York State, New York City, Rhode Island, South Dakota, Vermont, Washington, West Virginia, and Wyoming.

\*\*\*\*\* Excludes California, Connecticut, DC, Florida, Illinois, Maine, Maryland, Massachusetts, New Hampshire, New Mexico, New York State, Rhode Island, Vermont, West Virginia, Wisconsin and Wyoming.

††††† Excludes Arizona, California, Connecticut, DC, Florida, Georgia, Hawaii, Illinois, Louisiana, Maine, Maryland, New Hampshire, New Mexico, New York State, North Carolina, Ohio, Rhode Island, Vermont, West Virginia, Wisconsin, and Wyoming.

§§§§§ In 2011, the most recent year for which the Guttmacher Institute has published data, abortions performed in California, Maryland, and New Hampshire accounted for 21% of all abortions counted through the Guttmacher Institute's national census of abortion providers (14).

¶¶¶¶¶ In 2011, the abortion counts that CDC obtained from DC and New Jersey were 58% and 57%, respectively, of the abortion counts that the Guttmacher Institute obtained for these areas through their national census of abortion providers (14).

\*\*\*\*\* In 2011, the abortion counts CDC obtained for Wyoming were <5% of the counts obtained for this state by the Guttmacher Institute through their national census of abortion providers. CDC counts for Hawaii were 48% of the Guttmacher Institute counts. CDC counts for Alaska, Arizona, Colorado, Connecticut, Delaware, Idaho, Iowa, Louisiana, Maine, Massachusetts, Michigan, Nevada, New Mexico, New York (city and state combined), Ohio, Oregon, and West Virginia were 65% to <90% of the Guttmacher Institute counts. All other areas with legal reporting requirements that provided data to CDC obtained counts that were at least 90% of the Guttmacher Institute counts (14).

††††† Because the sole distributor of mifepristone in the United States only sells this medication to licensed physicians, who must sign and return a prescriber's agreement, sales data from this company are not limited by individual state reporting requirements or the difficulties of identifying smaller providers within the wider medical community.

§§§§§ Recent estimates suggest that intended pregnancies account for <5% of all abortions (24), including those which presumably are performed for maternal medical indications and fetal abnormalities.

**FIGURE 1. Number, rate,\* and ratio† of abortions performed, by year — selected reporting areas,§ United States, 2003–2012**

\* Number of abortions per 1,000 women aged 15–44 years.

† Number of abortions per 1,000 live births.

§ Data are for 47 reporting areas; excludes California, Louisiana, Maryland, New Hampshire, and West Virginia.

**Alternate Text:** This figure is a line graph that presents the number, rate (the number of abortions per 1,000 women aged 15-44 years) and the ratio (the number of abortions per 1,000 live births) of abortions performed by year in 47 reporting areas, between 2003 and 2012.

**FIGURE 2. Percentage of total abortions, abortion rate,\* and abortion ratio,† by age group of women who obtained a legal abortion — selected reporting areas,§ United States, 2012**

\* Number of abortions per 1,000 women aged 15–44 years.

† Number of abortions per 1,000 live births.

§ Data are for 45 reporting areas; excludes seven reporting areas (California, District of Columbia, Florida, Maryland, New Hampshire, Vermont, and Wyoming) that did not report by age, or did not meet reporting standards.

**Alternate Text:** This figure is a bar graph that presents the percentage of total abortions, the abortion rate (the number of abortions per 1,000 women aged 15-44 years) and ratio (the number of abortions per 1,000 live births) by age group of the women who obtained a legal abortion in 45 selected reporting areas in the United States in 2012.

**FIGURE 3. Percentage\* distribution of gestational ages at time of abortion, by age of woman — selected reporting areas, † United States, 2012**

\* Based on the total number of abortions reported with known weeks of gestation.

† Data from 36 reporting areas; excludes 16 reporting areas (California, Connecticut, District of Columbia, Florida, Illinois, Kentucky, Maine, Maryland, Massachusetts, Nebraska, New Hampshire, New York State, Pennsylvania, Vermont, Wisconsin, and Wyoming) that did not report, did not report by age or gestational age, or did not meet reporting standards.

**Alternate Text:** This figure presents the percentage of abortions reported with known weeks of gestation, based on the total number of abortions reported with known weeks of gestation, by the age of the woman, in 36 reporting areas of the United States in 2012.

**TABLE 1. Number, rate,\* and ratio† of reported abortions — selected reporting areas, United States, 2003–2012**

Year	All reporting areas§			Continuously reporting areas¶		
	No.	Rate	Ratio	No.	%**	Rate
2003	848,163	16.1	245	826,036	97.4	16.1

<b>Total</b>	<b>699,202</b>	NA	NA	NA	NA	NA	NA

**Abbreviation:** NA = not applicable.

\* Number of abortions per 1,000 women aged 15–44 years.

† Number of abortions per 1,000 live births.

§ Additional details on the state in which abortions were provided, cross-tabulated by the state of maternal residence, are available at [http://www.cdc.gov/reproductivehealth/data\\_stats/Abortion.htm](http://www.cdc.gov/reproductivehealth/data_stats/Abortion.htm).

¶ State did not report; because numbers for this state are available only from other states where residents obtained abortions, meaningful statistics cannot be reported.

\*\* Because reporting is not mandatory, a complete count of abortions performed in the District of Columbia could not be obtained.

†† Reported by occurrence only; because abortion counts by residence for these reporting areas are available only from other states where residents obtained abortions, meaningful statistics cannot be reported.

§§ State reported abortion numbers for both in-state and out-of-state residents; for out-of-state residents, the state or area of residence was not provided.

¶¶ Counts are preliminary because of incomplete reporting from certain facilities.

\*\*\* Data from hospitals and licensed ambulatory care facilities only; because reporting is not mandatory for private physicians and women's centers, a complete count of abortions performed in New Jersey could not be obtained.

††† Total abortion count ≤20.

§§§ Abortion rates and ratios and percentage of abortions obtained by out-of-state residents were not calculated for Wyoming because results based on a small number of abortions are unstable.

\* Data from 45 reporting areas; excludes seven reporting areas (California, District of Columbia, Florida, Maine, Maryland, New Hampshire, and Wyoming) that did not report, did not report by age, or did not meet reporting standards.

† Percentages for the individual component categories might not add to 100 because of rounding.

§ Calculated as the number of abortions reported by known age divided by the sum of abortions reported by known and unknown age.

¶ Cell details not displayed because of small numbers (N = 1–4).

\*\* Includes residents only.

†† Data from hospitals and licensed ambulatory care facilities only; because reporting is not mandatory for private physicians and women's centers, information could not be obtained for all abortions performed in New Jersey.

§§ Percentage based on a total of 616,075 abortions reported among the areas that met reporting standards for age.

¶¶ Number of abortions obtained by women in a given age group per 1,000 women in that same age group. Women aged 13–14 years were used as the denominator for the group of women aged <15 years, and women aged 40–44 years were used as the denominator for the group of women aged ≥40 years. Women aged 15–44 years were used as the denominator for the overall rate. For each state, abortions for women of unknown age were distributed according to the distribution of abortions among women of known age for that state.

\*\*\* Number of abortions obtained by women in a given age group per 1,000 live births to women in that same age group. For each state, abortions for women of unknown age were distributed according to the distribution of abortions among women of known age for that state.

\* Data from 42 reporting areas; by year, these reporting areas 96%–98% of all abortions reported to CDC by age during 2003–2012. Excludes 10 reporting areas (California, District of Columbia, Florida, Louisiana, Maine, Maryland, New Hampshire, West Virginia, Vermont, and Wyoming) that did not report, did not report by age, or did not meet reporting standards for ≥1 year.

† Number of abortions obtained by women in a given age group per 1,000 women in that same age group. Adolescents aged 13–14 years were used as the denominator for the group of adolescents aged <15 years, and women aged 40–44 years were used as the denominator for the group of women aged ≥40 years. For each state, abortions for women of unknown age were distributed according to the distribution of abortions among women of known age for that state.

§ Number of abortions obtained by women in a given age group per 1,000 live births to women in that same age group. For each state, abortions for women of unknown age were distributed according to the distribution of abortions among women of known age for that state.

\* Gestational age based on the clinician's estimate (Alabama, Alaska, Arizona, Colorado, Georgia, Hawaii, Idaho, Indiana, Iowa, Kansas, Kentucky, Louisiana, Michigan, Minnesota, Montana, Nevada, New Mexico, New York City, North Carolina, North Dakota, Ohio, Oregon, Rhode Island, South Carolina, South Dakota, Tennessee, Texas, Utah, Vermont, Virginia, Washington, and West Virginia); gestational age calculated from the last normal menstrual period (Arkansas and Oklahoma); method of determining gestational age not specified (Delaware, Mississippi, Missouri, and New Jersey).

† Data are from 38 reporting areas; excludes 14 areas (California, Connecticut, District of Columbia, Florida, Illinois, Maine, Maryland, Massachusetts, Nebraska, New Hampshire, New York State, Pennsylvania, Wisconsin, and Wyoming) that did not report, did not report by gestational age, or did not meet reporting standards.

§ Percentages for the individual component categories might not add to 100 because of rounding.

¶ Calculated as the number of abortions reported by known gestational age divided by the sum of abortions reported by known and unknown gestational age.

\*\* Cell details not displayed because of small numbers (N = 1–4).

†† Data from hospitals and licensed ambulatory care facilities only; because reporting is not mandatory for private physicians and women's centers, information could not be obtained for all abortions performed in New Jersey.

§§ Percentage based on a total of 469,892 abortions reported among the areas that met reporting standards for gestational age.

\* Gestational age based on the clinician's estimate (Alabama, Alaska, Arizona, Colorado, Georgia, Hawaii, Idaho, Indiana, Iowa, Kansas, Kentucky, Louisiana, Michigan, Minnesota, Montana, Nevada, New Mexico, New York City, North Carolina, North Dakota, Ohio, Oregon, Rhode Island, South Carolina, South Dakota, Tennessee, Texas, Utah, Vermont, Virginia, Washington, and West Virginia); gestational age calculated from the last normal menstrual period (Arkansas and Oklahoma); method of determining gestational age not specified (Delaware, Mississippi, Missouri, and New Jersey).

† Data are from 38 reporting areas; excludes 14 areas (California, Connecticut, District of Columbia, Florida, Illinois, Maine, Maryland, Massachusetts, Nebraska, New Hampshire, New York State, Pennsylvania, Wisconsin, and Wyoming) that did not report, did not report by gestational age, or did not meet reporting standards.

§ Percentages for the individual component categories might not add to 100 because of rounding.

¶ Data from hospitals and licensed ambulatory care facilities only; because reporting is not mandatory for private physicians and women's centers, information could not be obtained for all abortions performed in New Jersey.

**TABLE 10. Reported abortions obtained at ≤13 weeks' gestation, by week of gestation and year — selected reporting areas,\* United States, 2003–2012**

**TABLE 11. (Continued) Reported abortions, by known method type and reporting area of occurrence — selected reporting areas,\* United States, 2012**

**Abbreviation:** NA = not available.

\* Data from 41 reporting areas; excludes 11 reporting areas (California, District of Columbia, Florida, Illinois, Louisiana, Maryland, Maine, New Hampshire, Tennessee, Wisconsin, and Wyoming) that did not report, did not report by method type, or did not meet reporting standards. Because Hawaii did not include medical abortion as a separate category on its reporting form, numbers and percentages including this method are based on 40 reporting areas.

† Includes aspiration curettage, suction curettage, manual vacuum aspiration, menstrual extraction, sharp curettage, and dilation and evacuation procedures.

§ Intrauterine instillations reported at ≤12 weeks' gestation are not presented with abortions reported by known method type.

¶ Percentages for the individual component categories might not add to 100 because of rounding, and because some areas report more than one method for each abortion.

\*\* Calculated as the number of abortions reported by known method type divided by the sum of abortions reported by known and unknown method type.

†† Cells details not displayed because of small numbers (N = 1–4).

§§ Numbers for curettage procedures at ≤13 weeks versus >13 weeks and for medical abortion at ≤8 weeks versus >8 weeks are not presented because gestational age data were not provided or were provided in incompatible categories.

¶¶ Numbers for medical abortion are not presented because medical abortion was not included as a separate category on the reporting form.

\*\*\* Data from hospitals and licensed ambulatory care facilities only; because reporting is not mandatory for private physicians and women's centers, information could not be obtained for all abortions performed in New Jersey.

††† Curettage abortions reported without a gestational age were distributed among the curettage categories according to the distribution of abortions performed by curettage at known gestational age.

§§§ Medical abortions reported without a gestational age were distributed among the medical abortion categories according to the distribution of medical abortions at known gestational age.

¶¶¶ Percentage based on a total of 544,215 abortions reported among the areas that met reporting standards for method type.

\*\*\*\* Excludes Hawaii because this state did not include medical abortion as a separate category on its reporting form.

†††† Percentage based on a total of 541,391 abortions reported among the areas that met reporting standards for method type and included medical abortion on their reporting form.

**TABLE 12. Reported abortions, by known race/ethnicity of women who obtained an abortion and reporting area of occurrence — selected reporting areas,\* United States, 2012**

<b>Abortion rate¶¶</b>	<b>7.7</b>		<b>27.8</b>		<b>15.7</b>		<b>15.0</b>		<b>12.6</b>	
<b>Abortion ratio***</b>	<b>127</b>		<b>435</b>		<b>243</b>		<b>190</b>		<b>197</b>	

\* Data from 27 reporting areas; excludes 25 reporting areas (Alaska, Arizona, California, Connecticut, District of Columbia, Florida, Hawaii, Illinois, Iowa, Louisiana, Maine, Maryland, Massachusetts, Nebraska, Nevada, New Hampshire, New Mexico, North Dakota, Pennsylvania, Oklahoma, Rhode Island, Vermont, Washington, Wisconsin, and Wyoming) that did not report, did not report by race/ethnicity, or did not meet reporting standards.

† Percentages for the individual component categories might not add to 100 because of rounding.

§ Calculated as the number of abortions reported by known race/ethnicity divided by the sum of abortions reported by known and unknown race/ethnicity.

¶¶ Data from hospitals and licensed ambulatory care facilities only; because reporting is not mandatory for private physicians and women's centers, information could not be obtained for all abortions performed in New Jersey.

\*\* Non-Hispanic categories include abortions for women whose ethnicity was reported as unknown; previous evaluation has shown that most reports without ethnicity are for non-Hispanic women.

†† Reporting form contains only one question for race and ethnicity; therefore, abortions reported for women of white, black, and other races (Asian and Native American) are not explicitly identified as non-Hispanic.

§§ Percentage based on a total of 428,358 abortions reported among the areas that met reporting standards for race/ethnicity.

¶¶ Number of abortions obtained by women in a given race/ethnicity group per 1,000 women in that same group. For each state, abortions for women of unknown race/ethnicity were distributed according to the distribution of abortions among women of known race/ethnicity for that state.

\*\*\* Number of abortions obtained by women in a given race/ethnicity group per 1,000 live births to women in that same race/ethnicity group. For each state, abortions for women of unknown race/ethnicity were distributed according to the distribution of abortions among women of known race/ethnicity for that state.

**Abortion ratio<sup>††</sup>**      **47**                      **396**                      **182**

\* Data from 36 reporting areas; excludes 16 areas (California, Connecticut, District of Columbia, Florida, Georgia, Maine, Maryland, Massachusetts, Nebraska, Nevada, New Hampshire, New York State, Rhode Island, Vermont, Washington, and Wyoming) that did not report, did not report by marital status, or did not meet reporting standards.

† Percentages for the individual component categories might not add to 100 because of rounding.

§ Calculated as the number of abortions reported by known marital status divided by the sum of abortions reported by known and unknown marital status.

¶ Data from hospitals and licensed ambulatory care facilities only; because reporting is not mandatory for private physicians and women's centers, information could not be obtained for all abortions performed in New Jersey.

\*\* Percentage based on a total of 489,411 abortions reported among the areas that met reporting standards for marital status.

†† Number of abortions obtained by women by marital status per 1,000 live births to women of the same marital status. For each state, abortions for women of unknown marital status were distributed according to the distribution of abortions among women of known marital status for that state.

**TABLE 16. Reported abortions, by known number of previous live births and reporting area of occurrence — selected reporting areas,\* United States, 2012**

\* Number of legal induced abortion-related deaths per 100,000 reported legal induced abortions. Because a substantial number of legal induced abortions occurred outside reporting areas that provided data to CDC, national case-fatality rates (i.e., number of legal induced abortion-related deaths per 100,000 reported legal induced abortions in the United States) were calculated with denominator data from a more complete source (14). Case-fatality rates were computed for consecutive 5-year periods during 1973–2007 and then during a 4-year period during 2008–2011, because rates based on  $\leq 20$  cases are highly variable (36).

† Certain numbers might differ from those in reports published previously because additional information has been supplied to CDC subsequent to publication.

§ An abortion is defined as "legal" if it was performed by a licensed clinician.

¶ An abortion is defined as "illegal" if it was performed by any person other than a licensed clinician.

\*\* Unknown whether abortion was induced or spontaneous.
